Task Description #1 (Sorting – Merge Sort Implementation)

Prompt:
create a function merge_sort(arr) that sorts a list in ascending order. include time complexity and space complexity in the function docstring. Verify the generated code with test cases.

Code:

```python
def merge_sort(arr):
    """
    Sort a list in ascending order using the merge sort algorithm.

    Time Complexity: O(n log n) - divides the list in half at each level (log n levels)
                     and merges n elements at each level.
    Space Complexity: O(n) - additional temporary arrays used during merging;
                      recursion stack depth is O(log n) but dominant space is the
                      auxiliary arrays of size proportional to n.
    """
    if len(arr) <= 1:
        return arr

    mid = len(arr) // 2
    left = merge_sort(arr[:mid])
    right = merge_sort(arr[mid:])

    return _merge(left, right)

def _merge(left, right):
    """Merge two sorted lists into one sorted list."""
    result = []
    i = j = 0

    while i < len(left) and j < len(right):
        if left[i] <= right[j]:
            result.append(left[i])
            i += 1
        else:
            result.append(right[j])
            j += 1

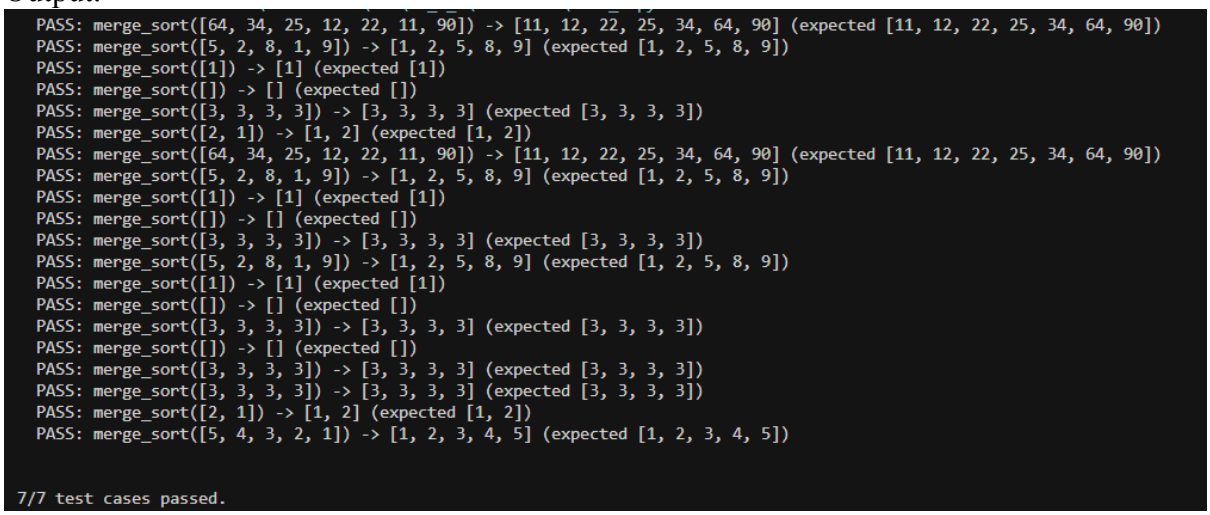
    result.extend(left[i:])
    result.extend(right[j:])
    return result

if __name__ == "__main__":
    # Test cases
    test_cases = [
        ([64, 34, 25, 12, 22, 11, 90], [11, 12, 22, 25, 34, 64, 90]),
        ([5, 2, 8, 1, 9], [1, 2, 5, 8, 9]),
        ([1], [1]),
        ([], []),
        ([3, 3, 3, 3], [3, 3, 3, 3]),
        ([2, 1], [1, 2]),
        ([5, 4, 3, 2, 1], [1, 2, 3, 4, 5]),
    ]

    passed = 0
    for arr, expected in test_cases:
        result = merge_sort(arr.copy())
        status = "PASS" if result == expected else "FAIL"
        if status == "PASS":
            passed += 1
        print(f"  {status}: merge_sort({arr}) -> {result} (expected {expected})")

    print(f"\n{passed}/{len(test_cases)} test cases passed.")
```

Output:



Task Description #2 (Searching – Binary Search with AI

Prompt:
create a function binary_search(arr, target) returning the index of the target or -1 if not found. Include docstrings explaining best, average, and worst-case complexities.Test with various inputs.

Code:

```python
def binary_search(arr, target):
    """
    Time Complexity
    ---------------
    - Best case: O(1)
        When the target is found at the middle position on the first comparison.
    - Average case: O(log n)
        On average, the search space is halved repeatedly until the target is
        found or the search space is empty.
    - Worst case: O(log n)
        When the target is not present or is only found after reducing the
        search space to size 1.

    Space Complexity
    ----------------
    - O(1)
        The algorithm uses a constant amount of extra space (iterative version).
    """
    left, right = 0, len(arr) - 1

    while left <= right:
        mid = (left + right) // 2
        if arr[mid] == target:
            return mid
        elif arr[mid] < target:
            left = mid + 1
        else:
            right = mid - 1

    return -1

if __name__ == "__main__":

Single element, target 5  -> index: -1
```

SR UNIVERSITY

Task Description #3: Smart Healthcare Appointment Scheduling System

Prompt:

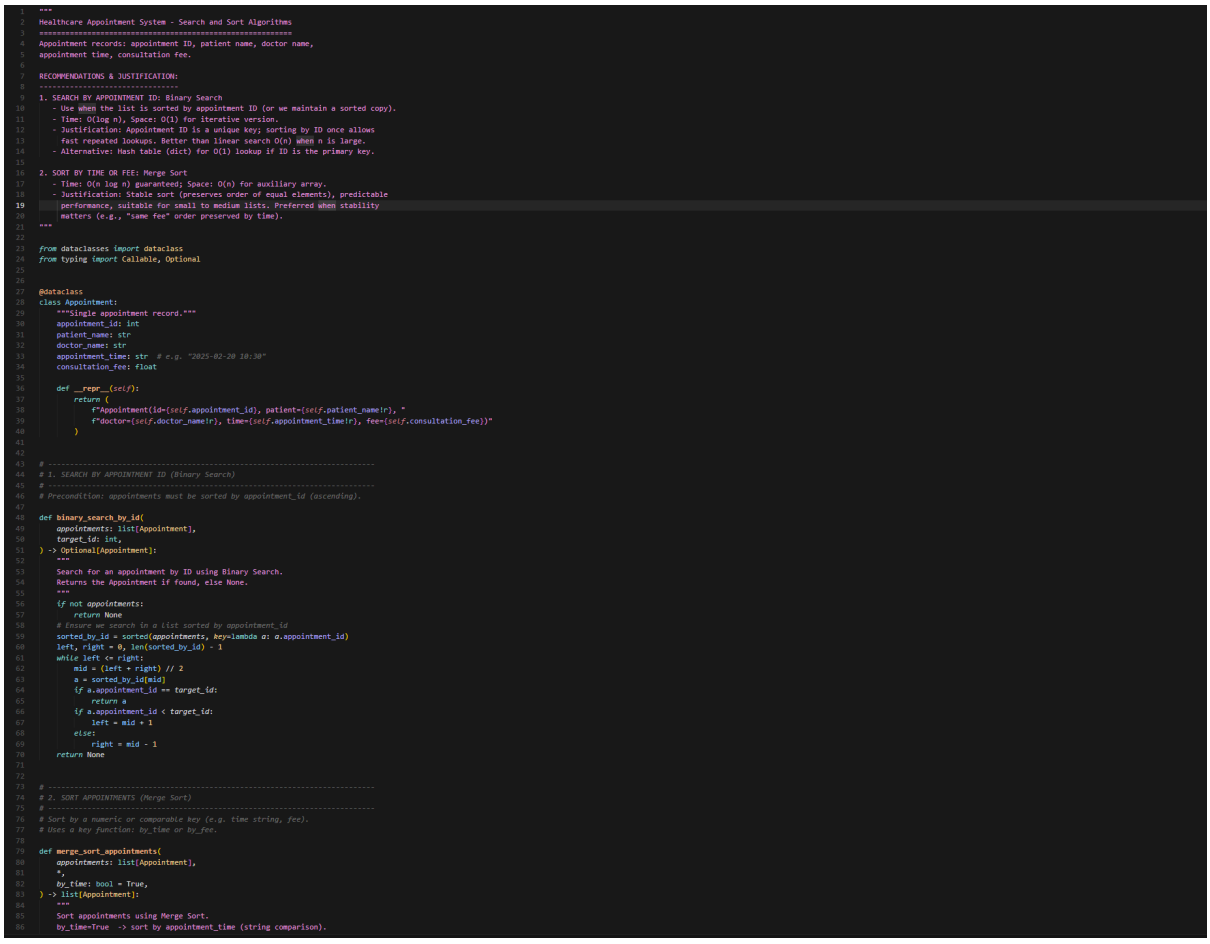
A healthcare platform maintains appointment records containing appointment ID, patient name, doctor name, appointment time, and consultation fee. The system needs to:

1. Search appointments using appointment ID.
2. Sort appointments based on time or consultation fee.

Tasks

• recommend suitable searching and sorting algorithms.
• Justify the selected algorithms.
• Implement the algorithms in Python.

Code:



```
"""
Healthcare Appointment System - Search and Sort Algorithms
==========================================================
Appointment records: appointment ID, patient name, doctor name,
appointment time, consultation fee.

RECOMMENDATIONS & JUSTIFICATION:
--------------------------------
1. SEARCH BY APPOINTMENT ID: Binary Search
   - Use when the list is sorted by appointment ID (or we maintain a sorted copy).
   - Time: O(log n), Space: O(1) for iterative version.
   - Justification: Appointment ID is a unique key; sorting by ID once allows
     fast repeated lookups. Better than linear search O(n) when n is large.
   - Alternative: Hash table (dict) for O(1) lookup if ID is the primary key.

2. SORT BY TIME OR FEE: Merge Sort
   - Time: O(n log n) guaranteed; Space: O(n) for auxiliary array.
   - Justification: Stable sort (preserves order of equal elements), predictable
     performance, suitable for small to medium lists. Preferred when stability
     matters (e.g., "same fee" order preserved by time).
"""

from dataclasses import dataclass
from typing import Callable, Optional

@dataclass

Task Description #4: Railway Ticket Reservation System Scenario

Prompt:
A railway reservation system stores booking details such as ticket ID, passenger name, train number, seat number, and travel date. The system must:
1. Search tickets using ticket ID.
2. Sort bookings based on travel date or seat number.
Tasks
• Identify efficient algorithms.
• Justify the algorithm choices.
• Implement searching and sorting in Python.

Code:

```python
"""
Railway Reservation System
Implements efficient search by ticket ID and sort by travel date or seat number.
"""

from dataclasses import dataclass
from datetime import date
from typing import Optional

@dataclass
class Booking:
    """Represents a single railway booking."""
    ticket_id: str
    passenger_name: str
    train_number: str
    seat_number: str
    travel_date: date

    def __str__(self):
        return (
            f"Ticket: {self.ticket_id} | {self.passenger_name} | "
            f"Train: {self.train_number} | Seat: {self.seat_number} | "
            f"Date: {self.travel_date}"
        )

class RailwayReservationSystem:
    """
    Railway reservation system with:
    - O(1) average-case search by ticket ID (hash table)
    - O(n log n) sort by travel date or seat number (Timsort via sorted())
    """

    def __init__(self):
        # List for ordered iteration and sorting
        self._bookings: list[Booking] = []

Task Description #5: Smart Hostel Room Allocation System

Prompt:
A hostel management system stores student room allocation details including student ID, room number, floor, and allocation date. The system needs to:
1. Search allocation details using student ID.
2. Sort records based on room number or allocation date.
Tasks
• suggest optimized algorithms.

• Justify the selections.
• Implement the solution in Python.

Code:

```python
"""
Hostel Management System - Lab 2.2
Stores student room allocation details with optimized search and sort operations.
"""

from dataclasses import dataclass
from datetime import date
from typing import Optional

@dataclass
class AllocationRecord:
    """Single room allocation record."""
    student_id: str
    room_number: int
    floor: int
    allocation_date: date

    def __str__(self):
        return (
            f"Student ID: {self.student_id}, Room: {self.room_number}, "
            f"Floor: {self.floor}, Date: {self.allocation_date}"
        )

class HostelManager:

    def list_all(self) -> list[AllocationRecord]:
        """Return all records in insertion order."""
        return list[AllocationRecord](self._records)

# ----- Algorithm summary and justification -----
"""
ALGORITHM CHOICES & JUSTIFICATION
---------------------------------

1. SEARCH BY STUDENT ID
   - Chosen: Hash table (Python dict) keyed by student_id
   - Time: O(1) average lookup
   - Justification:
     * Each student has at most one current allocation, so student_id is a
       natural unique key.
     * Hash table gives constant-time access by key without scanning.
     * Alternatives rejected:
       - Linear search O(n): poor for many records.
       - Binary search O(log n): would require keeping list sorted by
         student_id and extra bookkeeping when adding/removing.

2. SORT BY ROOM NUMBER / ALLOCATION DATE
   - Chosen: Timsort via sorted(iterable, key=...)
   - Time: O(n log n), stable
   - Justification:
     * We need to sort on different keys (room number, date) on demand.
     * Timsort is Python's default; it is stable and efficient for
       partially ordered data.
     * Keeping two sorted copies (by room and by date) would give O(log n)
       insertion but double storage and more complex updates; for typical
       hostel size, sorting when needed is simpler and fast enough.
"""
```

```python

def main():
    """Demo: add allocations, search by student ID, sort by room and date."""
    from datetime import date

    manager = HostelManager()

    # Add sample allocations
    manager.add_allocation("S001", 101, 1, date(2024, 1, 15))
    manager.add_allocation("S002", 205, 2, date(2024, 2, 1))
    manager.add_allocation("S003", 102, 1, date(2024, 1, 20))
    manager.add_allocation("S004", 201, 2, date(2024, 1, 10))

    print("--- Search by Student ID ---")
    for sid in ["S002", "S999"]:
        rec = manager.search_by_student_id(sid)
        print(f"  {sid}: {rec if rec else 'Not found'}")

    print("\n--- Sorted by Room Number ---")
    for r in manager.get_sorted_by_room_number():
        print(f"  {r}")

    print("\n--- Sorted by Allocation Date ---")
    for r in manager.get_sorted_by_allocation_date():
        print(f"  {r}")

Task Description #6: Online Movie Streaming Platform

Prompt:
A streaming service maintains movie records with movie ID, title, genre, rating, and release year. The platform needs to:
1. Search movies by movie ID.
2. Sort movies based on rating or release year.

SR UNIVERSITY

Tasks

- Recommend searching and sorting algorithms.
- Justify the chosen algorithms.
- Implement Python functions.

Code:

```python
"""
Streaming Service - Movie Records
Search by movie ID | Sort by rating or release year
"""

from typing import List, Optional, Literal

# ---------------------------------------------------------------------------
# Algorithm recommendations & justification
# ---------------------------------------------------------------------------
"""
SEARCH BY MOVIE ID:
  Algorithm: Binary Search
  Justification:
  - Movie IDs are unique and comparable → sorted list by ID is well-defined.
  - Time: O(log n) per lookup vs O(n) for linear search → efficient for large catalogs.
  - Space: O(1) extra; no need for a separate hash structure if we keep one list sorted by ID.
  - Alternative: Hash table (dict) gives O(1) average lookup; use when ID lookups dominate
    and the list is not already sorted by ID.

SORT BY RATING OR RELEASE YEAR:
  Algorithm: Merge Sort
  Justification:
  - Stable sort: preserves order of movies with equal rating/year (e.g. by title or ID).
  - Time: O(n log n) in all cases; predictable for streaming-sized datasets.
  - No worst-case O(n^2) as in naive Quick Sort; suitable for user-facing ordering.
  - Works well with linked/record data; easy to sort by different keys (rating, year).
"""

def binary_search_by_id(movies: List[dict], movie_id: int) -> Optional[dict]:

Task Description #7: Smart Agriculture Crop Monitoring System
Prompt:
An agriculture monitoring system stores crop data with crop ID, crop name, soil moisture level, temperature, and yield estimate. Farmers need to:
1. Search crop details using crop ID.
2. Sort crops based on moisture level or yield estimate.
Tasks
• use reasoning to select algorithms.
• Justify algorithm suitability.
• Implement searching and sorting in Python.

Code:

```python
"""
Agriculture Monitoring System
Stores crop data and supports search by crop ID and sort by moisture or yield.
"""

from dataclasses import dataclass
from typing import Optional

# ---------------------------------------------------------------------------
# Algorithm selection and justification
# ---------------------------------------------------------------------------
#
# SEARCH BY CROP ID:
#   Chosen: Hash table (dict) index for O(1) lookup by crop_id.
#   - Crop ID is unique and used for direct lookups.
#   - Alternatives: linear search O(n), binary search O(log n) on sorted list.
#   - Hash table is best here: constant-time access, no need to sort by ID
#     or scan the list. Suited when key is unique and lookups are frequent.
#
# SORT BY MOISTURE OR YIELD:
#   Chosen: Python's sorted() (Timsort) with key function — O(n log n), stable.
#   - We need to sort by different fields (moisture, yield) without changing
#     the original list order for display.
#   - Timsort is efficient, stable (preserves order of equal elements), and
#     well-suited for real-world data. No need for manual quicksort/mergesort.
# ---------------------------------------------------------------------------

Done.
```

Task Description #8: Airport Flight Management System

Prompt:
An airport system stores flight information including flight ID, airline name, departure time, arrival time, and status. The system must:
1. Search flight details using flight ID.
2. Sort flights based on departure time or arrival time.
Tasks
• recommend algorithms.
• Justify the algorithm selection.
• Implement searching and sorting logic in Python.

Code:

SR UNIVERSITY

```python
"""
Airport Flight Information System
- Search flight details by flight ID
- Sort flights by departure time or arrival time
"""

from datetime import datetime
from typing import Optional

# ============= ALGORITHM RECOMMENDATIONS & JUSTIFICATION =============
#
# 1. SEARCH BY FLIGHT ID
#    Recommended: Hash Table (Python dict) for O(1) average lookup
#    Justification:
#     - Flight ID is a unique key; hash table gives constant-time lookup.
#     - No need to keep list sorted by ID just for search.
#     - Alternative: Binary Search O(log n) if list were sorted by ID;
#       Linear Search O(n) is simple but slow for many flights.
#
# 2. SORT BY DEPARTURE/ARRIVAL TIME
#    Recommended: Timsort (Python's sorted()) — O(n log n), stable
#    Justification:
#     - Timsort is Python's default; optimal for real-world data (handles
#       partial order, few comparisons).
#     - Stable sort preserves relative order of equal keys (e.g. same time).
#     - Alternatives: Merge Sort O(n log n) stable; Quick Sort O(n log n)
#       average but not stable.
# ======================================================================
